

IT314 - Software Engineering

Project Instructions

Now that your project has been assigned, here's what your group needs to do to get started. All groups must follow the **Agile (SCRUM)** methodology for the entire development process.

1. Identify Stakeholders and End Users

List everyone who has a stake in your system end users, admins, any third parties who interact with or are affected by it.

2. Identify Elicitation Techniques

For each stakeholder identified above, decide which requirement-elicitation technique(s) you'll use (e.g., interviews, surveys, observation, brainstorming, document analysis) and be ready to justify *why* that technique fits that stakeholder.

3. Apply the Elicitation Techniques

Actually use those techniques to gather requirements covering:

- Functional requirements
- Non-functional requirements
- Domain requirements

4. Write User Stories (Product Backlog)

For each requirement, write a user story with both the **front of the card** (role, goal, benefit) and the **back of the card** (acceptance criteria/conditions of satisfaction). Together these form your Product Backlog.

5. Create EPICs (grouped into Sprints)

Organize your user stories into EPICs, and use those to generate Sprints.

6. Identify and Resolve Conflicts

Check for conflicting requirements or user stories across stakeholders/EPICs, and document how you resolved them.

7. Start Sprint 1

Begin development for Sprint 1. As part of this sprint, prepare a **concept poster as a visual guide/reference point** for your project's development.

Mandatory Collaboration Tools

GitHub - All development must happen through GitHub. Every team member must be added as a contributor, and commits should reflect actual individual contribution (the person who did the work makes the commit - this will be checked later).

Slack - All team communication should happen over Slack, not personal chat apps. Keep discussions, decisions, and updates visible there.
